# Administrivia

- ▶ **Class web page:** <http://imag-moodle.e.ujf-grenoble.fr/course/view.php?id=104>
  - ▶ All assignments, handouts, lecture notes on-line
  - ▶ **Not yet up-to-date (I'm no more admin for now)**
- ▶ **References**
  - ▶ Textbook: *Operating System Concepts, 8th Edition*, by Silberschatz, Galvin, and Gagne
  - ▶ Slides heavily inspired by those from “CS140: Operating Systems by **David Mazieres** (Stanford)” and “Mosig1 by **Arnaud Legrand**”. Many thanks to them!!!
- ▶ **Staff email address:** {[Vincent.Danjean](mailto:Vincent.Danjean@imag.fr), [Florent.Bouchez](mailto:Florent.Bouchez@imag.fr), [Nicolas.Fournel](mailto:Nicolas.Fournel@imag.fr)}@imag.fr
  - ▶ Add [M1-CSE] to the subject of your emails (else, can be missed)
- ▶ **Key dates:**
  - ▶ Lectures: Monday & Tuesday 9:45–11:15, F320, F022
  - ▶ Practical Sessions: Wednesday 8:00–11:15, (F319/F321 + F203)  
**Only two groups, ADE not up-to-date**
  - ▶ Midterm: to be determined,
  - ▶ Final: to be determined

# Course goals

- ▶ **Introduce you to operating system concepts**
  - ▶ Hard to use a computer without interacting with OS
  - ▶ Understanding the OS makes you a more effective programmer
  - ▶ The first minutes of the lecture can be devoted to re-explain some parts of the previous lecture.
  - ▶ I can also come earlier if you have questions but you should send me an email before.
- ▶ **Cover important systems concepts in general**
  - ▶ Caching, concurrency, memory management, I/O, protection
- ▶ **Teach you to deal with larger software systems**
- ▶ **Prepare you to take graduate OS classes (M1 Principles of Computer Networks, M2 Parallel Systems, Distributed Systems, ...)**

# Programming Assignments

- ▶ **Among the different practical sessions, some of them might be graded:**
  - ▶ A simple memory allocator.
  - ▶ A Synchronization problem.
  - ▶ etc.
- ▶ **Implement projects in groups of up to 2 people**
- ▶ **No incompletes**
  - ▶ Please, please, please turn in working code, or **no credit** here
- ▶ **Means design and style matter a lot**
  - ▶ Large software systems not just about producing working code
  - ▶ Need to produce code other people can understand
  - ▶ That's why we have group projects

# Style

- ▶ **Must turn in a design document along with code**
- ▶ **CAs will manually inspect code for correctness**
  - ▶ E.g., must actually implement the design
  - ▶ Must handle corner cases (e.g., handle `malloc` failure)
- ▶ **Will deduct points for error-prone code w/o errors**
  - ▶ Don't use global variables if automatic ones suffice
  - ▶ Don't use deceptive names for variables
- ▶ **Code must be easy to read**
  - ▶ Indent code, keep lines and (when possible) functions short
  - ▶ Use a uniform coding style (try to match existing code)
  - ▶ Put comments on structure members, globals, functions
  - ▶ Don't leave in reams of commented-out garbage code

# Assignment requirements

- ▶ **Do not look at other people's solutions to projects**
- ▶ **Can read but don't copy other OSES**
  - ▶ E.g., Linux, Open/FreeBSD, etc.
- ▶ **Cite any code that inspired your code**
  - ▶ As long as you cite what you used, it's not cheating
  - ▶ Worst case will be the "Section Disciplinaire"
- ▶ **Projects due on the next Tuesday at noon (see date on moodle)**
- ▶ **Ask me for extension if you run into trouble**

# Outline

Administrivia

## Introduction to Operating Systems

Main Goals

- Abstraction

- CPU protection

- Memory protection

- Efficient Use of Resources

- Recap

# What is an operating system?

- ▶ **Layer between applications and hardware**

- ▶ **Makes hardware useful to the programmer**
- ▶ **[Usually] Provides abstractions for applications**
  - ▶ Manages and hides details of hardware
  - ▶ Accesses hardware through low/level interfaces unavailable to applications
- ▶ **[Often] Provides protection**
  - ▶ Prevents one process/user from clobbering another

# Why study operating systems?

- ▶ **Operating systems are a maturing field**
  - ▶ Most people use a handful of mature OSeS
  - ▶ Hard to get people to switch operating systems
  - ▶ Hard to have impact with a new OS
- ▶ **High-performance servers are an OS issue**
  - ▶ Face many of the same issues as OSeS
- ▶ **Resource consumption is an OS issue**
  - ▶ Battery life, radio spectrum, etc.
- ▶ **Security is an OS issue**
  - ▶ Hard to achieve security without a solid foundation
- ▶ **New “smart” devices need new OSeS**
- ▶ **Web browsers increasingly face OS issues**

# Primitive Operating Systems

- ▶ **Just a library of standard services [no protection]**

- ▶ Standard interface above hardware-specific drivers, etc.
- ▶ **Simplifying assumptions**
  - ▶ System runs one program at a time
  - ▶ No bad users or programs (often bad assumption)
- ▶ **Problem: Poor utilization**
  - ▶ ...of hardware (e.g., CPU idle while waiting for disk)
  - ▶ ...of human user (must wait for each program to finish)

# Multitasking

- ▶ **Idea: Run more than one process at once**
  - ▶ When one process blocks (waiting for disk, network, user input, etc.) run another process
- ▶ **Problem: What can ill-behaved process do?**

# Multitasking

- ▶ **Idea: Run more than one process at once**
  - ▶ When one process blocks (waiting for disk, network, user input, etc.) run another process
- ▶ **Problem: What can ill-behaved process do?**
  - ▶ Go into infinite loop and never relinquish CPU
  - ▶ Scribble over other processes' memory to make them fail
- ▶ **OS provides mechanisms to address these problems**
  - ▶ *Preemption* – take CPU away from looping process
  - ▶ *Memory protection* – protect process's memory from one another

# Multi-user OSES

- ▶ Many OSES use protection to serve distrustful users
- ▶ Idea: With  $N$  users, system not  $N$  times slower
  - ▶ Users' demands for CPU, memory, etc. are bursty
  - ▶ Win by giving resources to users who actually need them
- ▶ What can go wrong?

# Multi-user OSes

- ▶ **Many OSes use protection to serve distrustful users**
- ▶ **Idea: With  $N$  users, system not  $N$  times slower**
  - ▶ Users' demands for CPU, memory, etc. are bursty
  - ▶ Win by giving resources to users who actually need them
- ▶ **What can go wrong?**
  - ▶ Users are gluttons, use too much CPU, etc. (need policies)
  - ▶ Total memory usage greater than in machine (must virtualize)
  - ▶ Super-linear slowdown with increasing demand (thrashing)

# Outline

Administrivia

Introduction to Operating Systems

Main Goals

- Abstraction

- CPU protection

- Memory protection

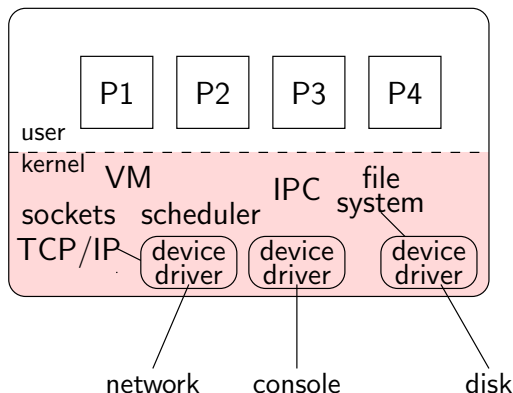

- Efficient Use of Resources

- Recap

# Protection

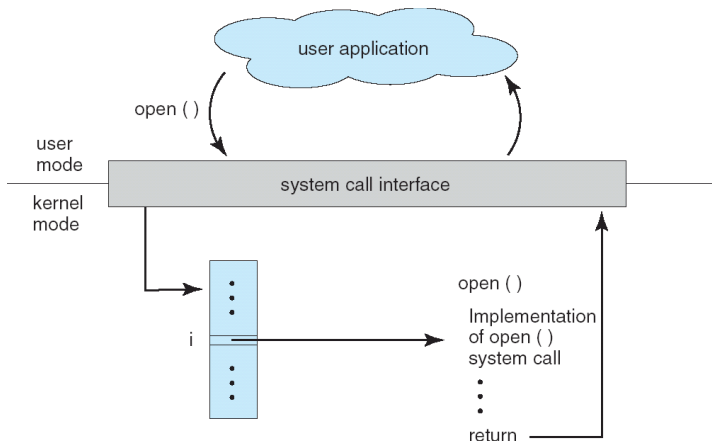

- ▶ **Mechanisms that isolate bad programs and people**
- ▶ **Pre-emption:**
  - ▶ Give application a resource, take it away if needed elsewhere
- ▶ **Interposition:**
  - ▶ Place OS between application and “stuff”
  - ▶ Track all pieces that application allowed to use (e.g., in table)
  - ▶ On every access, look in table to check that access legal
- ▶ **Privileged & unprivileged modes in CPUs :**
  - ▶ Applications unprivileged (user/unprivileged mode)
  - ▶ OS privileged (privileged/supervisor mode)
  - ▶ Protection operations can only be done in privileged mode

# Typical OS structure

- ▶ Most software runs as user-level processes (P[1-4])
- ▶ OS kernel runs in privileged mode **[shaded]**
  - ▶ Creates/deletes processes
  - ▶ Provides access to hardware

# System calls

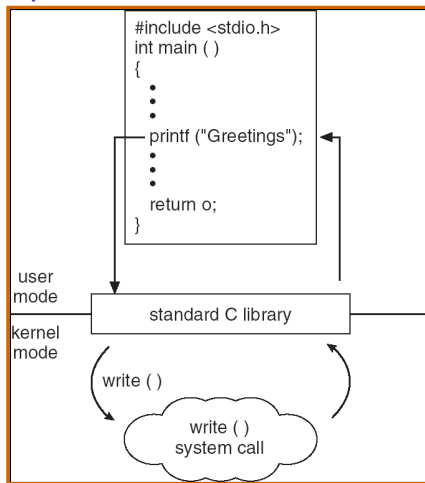

- ▶ **Applications can invoke kernel through system calls**
  - ▶ Special instruction transfers control to kernel
  - ▶ ... which dispatches to one of few hundred syscall handlers

# System calls (continued)

- ▶ **Goal: Do things app. can't do in unprivileged mode**
  - ▶ Like a library call, but into more privileged kernel code
- ▶ **Kernel supplies well-defined system call interface**
  - ▶ Applications set up syscall arguments and *trap* to kernel
  - ▶ Kernel performs operation and returns result
- ▶ **Higher-level functions built on syscall interface**
  - ▶ `printf`, `scanf`, `gets`, etc. all user-level code
- ▶ **Example: POSIX/UNIX interface**
  - ▶ `open`, `close`, `read`, `write`, ...

# System call example

- ▶ **Standard library implemented in terms of syscalls**
  - ▶ *printf* – in libc, has same privileges as application
  - ▶ calls *write* – in kernel, which can send bits out serial port

# Different system contexts

- ▶ **A system can typically be in one of several contexts**
- ▶ **User-level – running an application**
- ▶ **Kernel process context (“top half” in Unix)**
  - ▶ Running kernel code on behalf of a particular process
  - ▶ E.g., performing system call
  - ▶ Also exception (mem. fault, numeric exception, etc.)
  - ▶ Or executing a kernel-only process (e.g., network file server)
- ▶ **Kernel code not associated w. a process (“bottom half” in Unix)**
  - ▶ Timer interrupt (hardclock)
  - ▶ Device interrupt
  - ▶ “Softirqs”, “Tasklets”, ... in Linux
- ▶ **Context switch code – changing address spaces**

# Transitions between contexts

- ▶ **User → top half: syscall, page fault**
- ▶ **User/top half → device/timer interrupt: hardware**
- ▶ **Top half → user/context switch: return**
- ▶ **Top half → context switch: sleep**
- ▶ **Context switch → user/top half**

# CPU preemption

- ▶ **Protection mechanism to prevent monopolizing CPU**
- ▶ **E.g., kernel programs timer to interrupt every 10 ms**
  - ▶ Must be in supervisor mode to write appropriate I/O registers
  - ▶ User code cannot re-program interval timer
- ▶ **Kernel sets interrupt to vector back to kernel**
  - ▶ Regains control whenever interval timer fires
  - ▶ Gives CPU to another process if someone else needs it
  - ▶ Note: must be in supervisor mode to set interrupt entry points
  - ▶ No way for user code to hijack interrupt handler
- ▶ **Result: Cannot monopolize CPU with infinite loop**
  - ▶ At worst get  $1/N$  of CPU with  $N$  CPU-hungry processes

# Protection is not security

- ▶ **How can you monopolize CPU?**

# Protection is not security

- ▶ **How can you monopolize CPU?**

- ▶ **Use multiple processes**

- ▶ **Until recently, could wedge many OSes with**

  - `int main() { while(1) fork(); }`

  - ▶ Keeps creating more processes until system out of proc. slots

- ▶ **Other techniques: use all memory (chill program)**

- ▶ **Typically solved with technical/social combination**

  - ▶ Technical solution: Limit processes per user
  - ▶ Social: Reboot and yell at annoying users
  - ▶ Social: Pass laws (often debatable whether a good idea)

# Address translation

- ▶ **Protect mem. of one program from actions of another**
- ▶ **Definitions**
  - ▶ *Address space*: all memory locations a program can name
  - ▶ *Virtual address*: addresses in process' address space
  - ▶ *Physical address*: address of real memory
  - ▶ *Translation*: map virtual to physical addresses
- ▶ **Translation done on every load and store**
  - ▶ Modern CPUs do this in hardware for speed
- ▶ **Idea: If you can't name it, you can't touch it**
  - ▶ Ensure one process's translations don't include any other process's memory

# More memory protection

- ▶ **CPU allows kernel-only virtual addresses**
  - ▶ Kernel typically part of all address spaces, e.g., to handle system call in same address space
  - ▶ But must ensure apps can't touch kernel memory
- ▶ **CPU allows disabled virtual addresses**
  - ▶ Catch and halt buggy program that makes wild accesses
  - ▶ Make virtual memory seem bigger than physical (e.g., bring a page in from disk only when accessed)
- ▶ **CPU enforced read-only virtual addresses useful**
  - ▶ E.g., allows sharing of code pages between processes
  - ▶ Plus many other optimizations
- ▶ **CPU enforced execute disable of VAs**
  - ▶ Makes certain code injection attacks harder

# Resource allocation & performance

- ▶ **Multitasking permits higher resource utilization**
- ▶ **Simple example:**
  - ▶ Process downloading large file mostly waits for network
  - ▶ You play a game while downloading the file
  - ▶ Higher CPU utilization than if just downloading
- ▶ **Complexity arises with cost of switching**
- ▶ **Example: Say disk 1,000 times slower than memory**
  - ▶ 100 MB memory in machine
  - ▶ 2 Processes want to run, each use 100 MB
  - ▶ Can switch processes by swapping them out to disk
  - ▶ Faster to run one at a time than keep context switching

# Useful properties to exploit

## ► Skew

- 80% of time taken by 20% of code
- 10% of memory absorbs 90% of references
- Basis behind cache: place 10% in fast memory, 90% in slow, usually looks like one big fast memory

## ► Past predicts future (a.k.a. temporal locality)

- What's the best cache entry to replace?
- If past = future, then least-recently-used entry

## ► Note conflict between fairness & throughput

- Higher throughput (fewer cache misses, etc.) to keep running same process
- But fairness says should periodically preempt CPU and give it to next process

# Goals

## Main Goals of an OS:

- ▶ Provide **abstraction** of hardware through sound APIs
- ▶ Make **efficient** use of hardware
- ▶ Ensure **protection**
- ▶ Ensure **fairness**

You should always study the lectures (including this one) with these goals in mind.

We will see how these different issues are addressed when dealing with the different parts of a computer system (memory, CPU, storage, network, . . . ).

The course will be organized accordingly.

# Course Organization

## Memory (Virtual memory)

- ▶ Fragmentation and segmentation
- ▶ Pagination, caching

## CPU

- ▶ Processes & Threads
- ▶ Scheduling
- ▶ Concurrency, Synchronization & Communication

## Storage

- ▶ File systems
- ▶ Network file systems

## Network

- ▶ Distributed Systems

**Note:** Lectures will often take Unix as an example

- ▶ Most current and future OSes heavily influenced by Unix
- ▶ Windows is exception; we will mostly ignore it
