

# Introduction to Software Engineering

---

## Software architecture

Philippe Lalanda

[Philippe.lalanda@imag.fr](mailto:Philippe.lalanda@imag.fr)

<http://membres-liglab.imag.fr/lalanda/>

# Outline

---

- ❑ Definition
- ❑ Communication styles
  - ❑ Client / server style
  - ❑ Message-oriented style
  - ❑ Publish / subscribe style
  - ❑ Pipe and filter style
- ❑ Organization styles
  - ❑ Layered style
  - ❑ Shared memory style
- ❑ Conclusion

# Reminder: two levels of design

---

- ❑ Global design
  - ❑ Software architecture
    - ❑ Components
    - ❑ Connectors
- ❑ Detailed design
  - ❑ Programming concepts
    - ❑ Objects, structured types, ...
    - ❑ Methods, procedures, ...

# Software architecture

---

- ❑ An abstract specification expressed as components interacting through connectors
- ❑ Its purpose is not to be executable – it's a model
- ❑ It is a decomposition that has to meet requirements

# Example

---

**Legend**  
— C/S

# Software architecture - **specification**

---

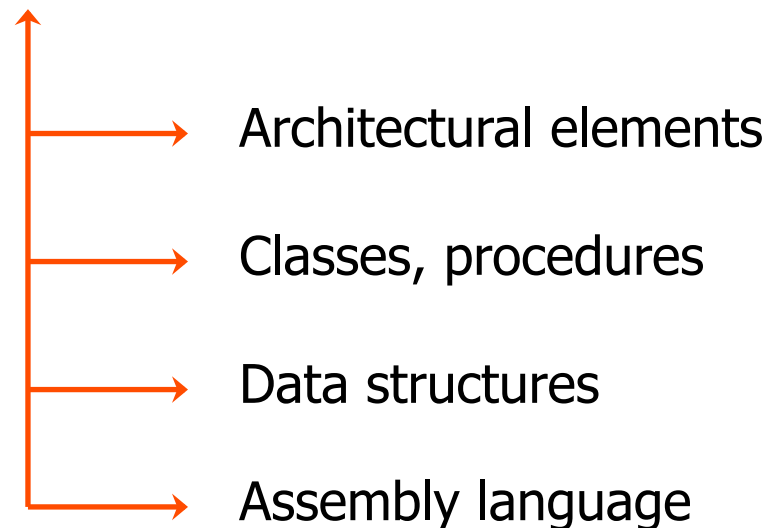

- ❑ An architecture defines the overall organization (structure) of the code to come
  - ❑ It is a guideline for designers / developers
- ❑ It must be precise
  - ❑ Choices are made
  - ❑ Not a (fuzzy) functional decomposition
- ❑ It is complete
  - ❑ Gives all necessary information for detailed design
    - ❑ Possibly performed by partners, remote teams, ...

# Software architecture - **abstraction**

---

- ❑ An additional level of abstraction
  - ❑ It does not bother with implementation details
  - ❑ It defines relevant properties of structuring elements
  - ❑ Not existing in current languages (packages ...)

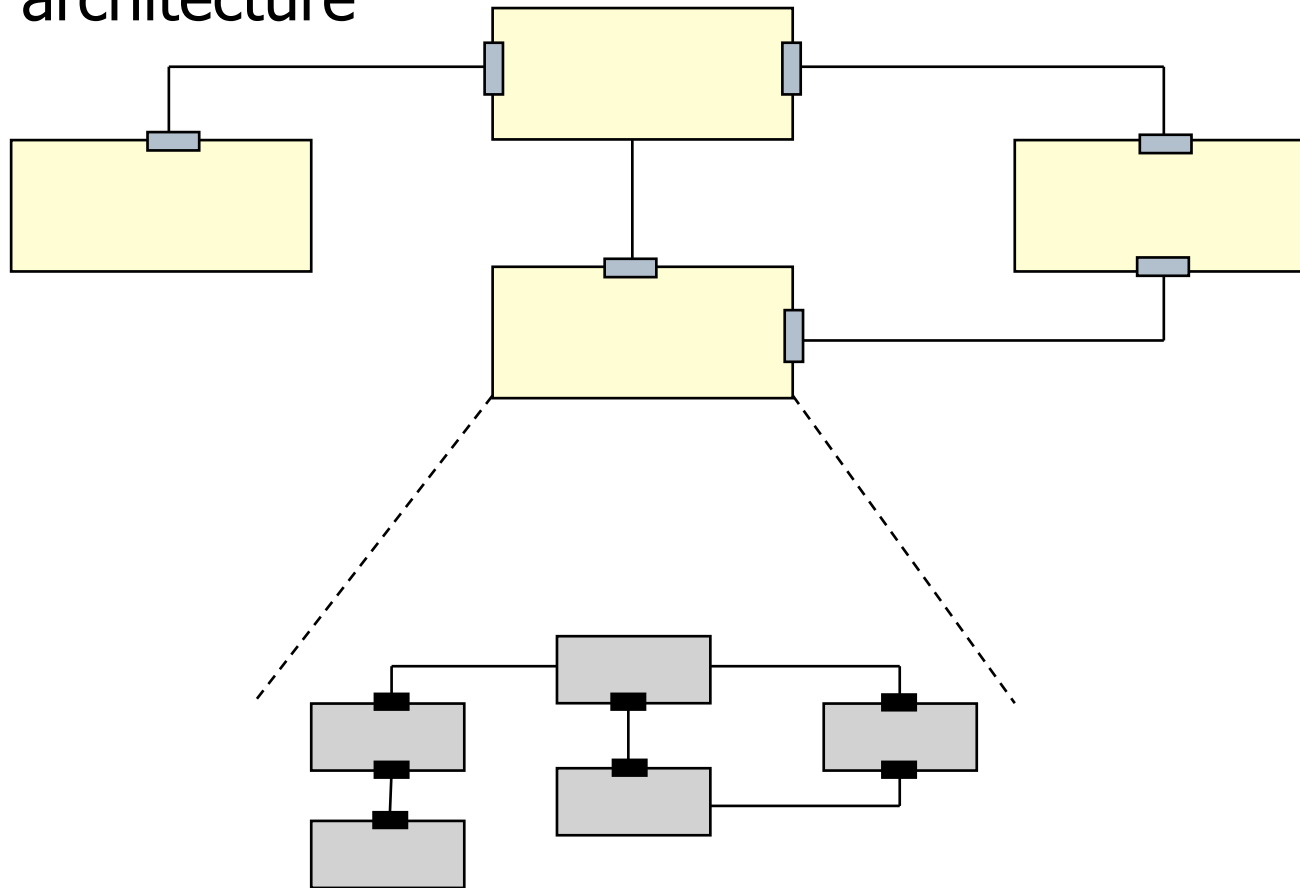

## **Abstraction**

# Software architecture - **abstractions**

---

Global architecture

Architecture of an element

# Software architecture - components

---

- ❑ Functional units specifications
  - ❑ Clearly defined, coherent, comprehensible
  - ❑ With functional dependencies
  - ❑ With properties, constraints

# Software architecture - connectors

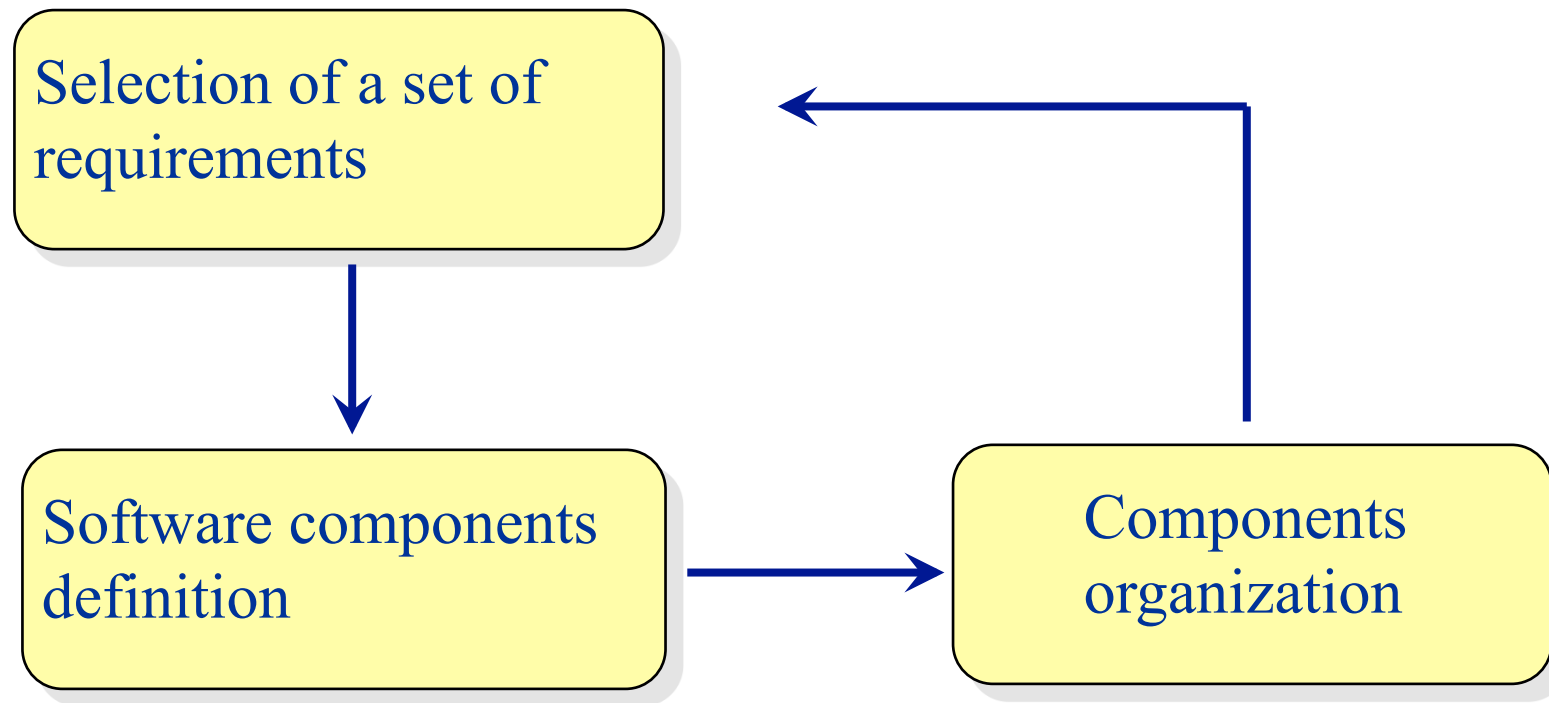

---

- ❑ First order objects
  - ❑ Defines interactions between components
  - ❑ Can be pretty complex
  - ❑ No specification language yet

# Designing software architecture

---

# Design challenge

---

- ❑ Selection of requirements
  - ❑ Find out relevant requirements at each iteration
- ❑ Definition/refinement of components
  - ❑ Driven by functional requirements and by the design context
  - ❑ Some are techniques, others are business specific
- ❑ Organization of components
  - ❑ Interaction patterns, rules, ...
  - ❑ Driven by non functional requirements

# Architectural styles

---

- ❑ Idea
  - ❑ Styles used in a recurrent way in successful systems should be reused
- ❑ Principles
  - ❑ Describe successful styles (books)
  - ❑ Learn them
  - ❑ Combine them to meet your project goals

# Outline

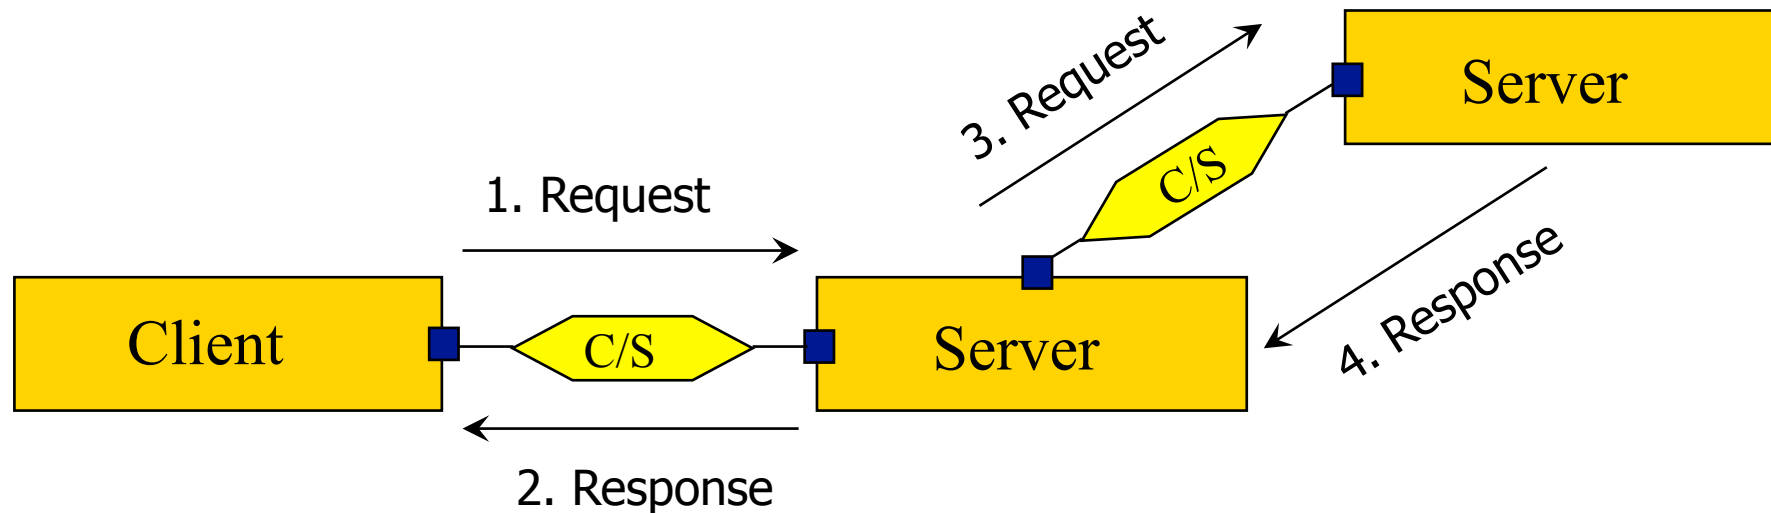

---

- ❑ Definition
- ❑ Communication styles
  - ❑ Client / server style
  - ❑ Message-oriented style
  - ❑ Publish / subscribe style
  - ❑ Pipe and filter style
- ❑ Organization styles
  - ❑ Layered style
  - ❑ Shared memory style
- ❑ Conclusion

# Client / server style

---

- ❑ Structure the system into components interacting through well defined functional interfaces
- ❑ Synchronous interactions, initiated by the client
- ❑ Interactions are deterministic and non continuous

# Style characterization

---

## Elements

- ❑ Clients: service requesters
- ❑ Servers: service providers
- ❑ Ports: functional interfaces
- ❑ Connectors: (R)PC calls

## Computing model

- ❑ Communication is initiated by clients.
- ❑ They ask for a service and wait for the answer.

## Constraints

No constraints on topology.

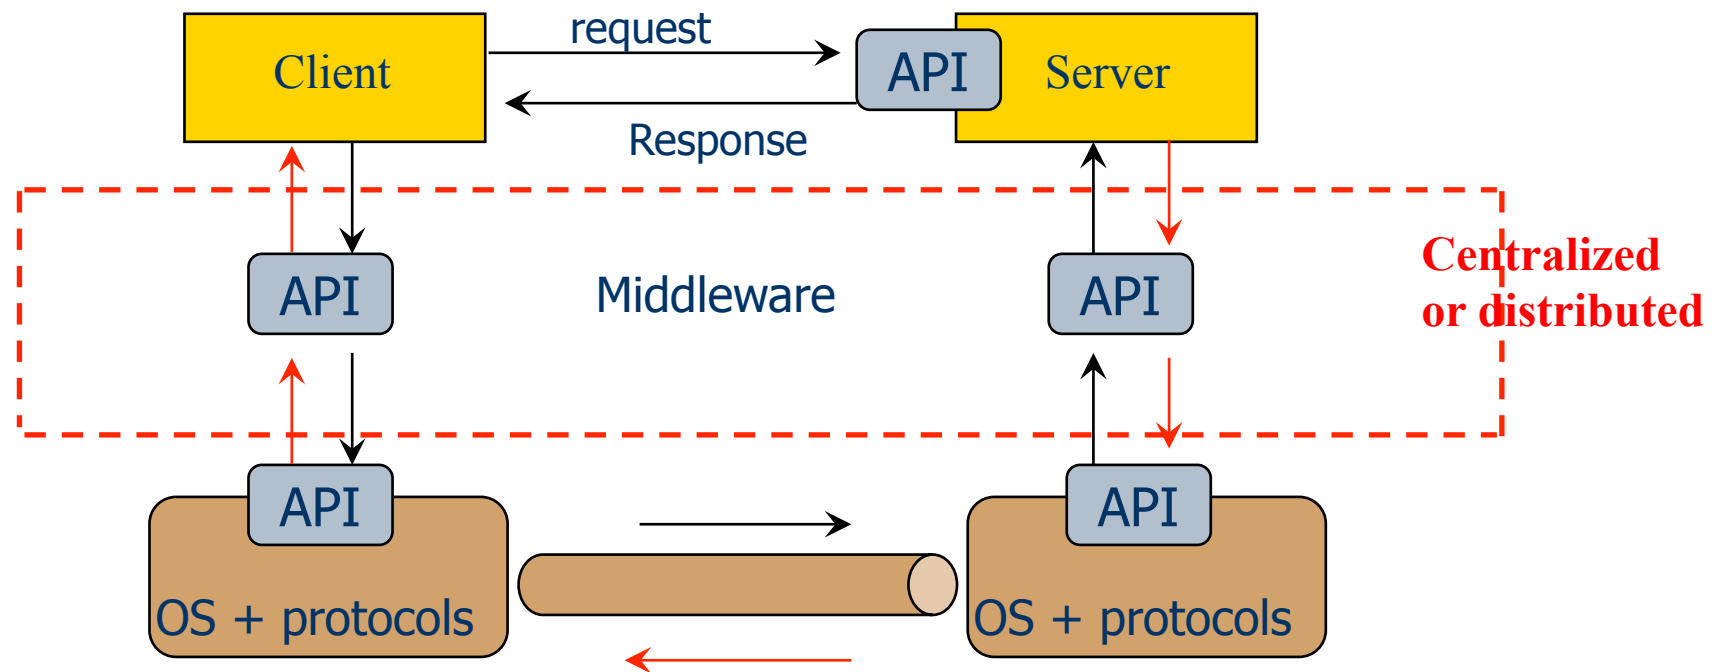

Possible constraints:

- limited number of clients
- service scheduling

# Implementation

- ❑ Use a middleware
  - ❑ To handle communication (mainly when distributed)
  - ❑ Can hide localizations, initiate / stop interactions, ...

# Advantages

---

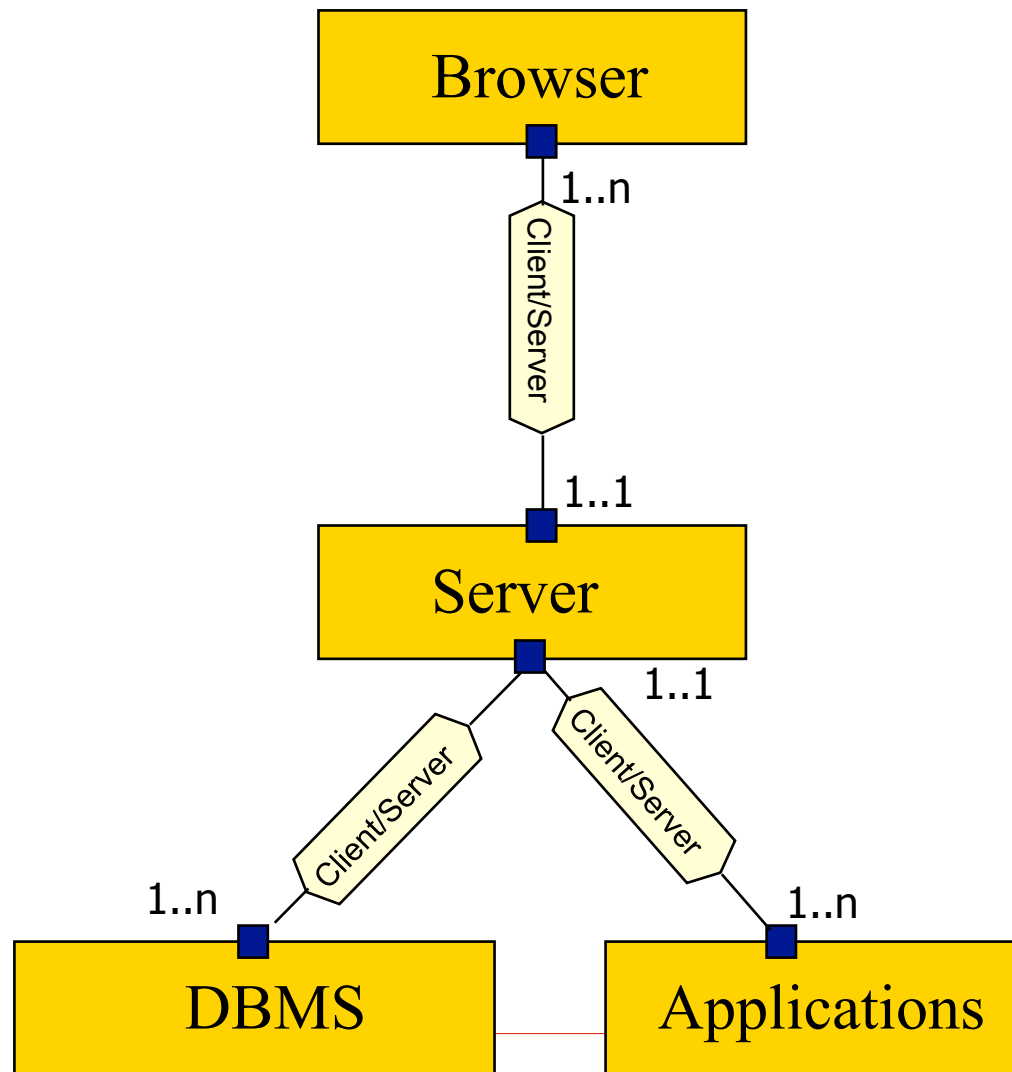

- ❑ Simple and clear
  - ❑ Easy to communicate
- ❑ Good SE practices
  - ❑ Strongly types APIs
    - ❑ Safer !
  - ❑ Encapsulation and information masking
    - ❑ Coherence and modularity
- ❑ Should favor test, debug, evolution

# Limits

---

- ❑ Performance
  - ❑ Communication cost
  - ❑ Several services might be called to meet a given goal
  - ❑ Scalable
- ❑ Reusability
  - ❑ Components dependencies
  - ❑ Non functional code in the components
- ❑ Distribution is complex
  - ❑ A middleware is rapidly necessary

# Example: Web-based systems

# Conclusion

---

- ❑ This is “classic” style which is used in many projects
  - ❑ Corresponds somehow to the state of the art in SE
  - ❑ Towards Component based software engineering
  
- ❑ Use it when
  - ❑ No heavy constraints on performance
  - ❑ APIs are known and can be typed
  - ❑ No massive data flow

# Outline

---

- ❑ Definition
- ❑ Communication styles
  - ❑ Client / server style
  - ❑ Message-oriented style
  - ❑ Publish / subscribe style
  - ❑ Pipe and filter style
- ❑ Organization styles
  - ❑ Layered style
  - ❑ Shared memory style
- ❑ Conclusion

# Message oriented style

---

- ❑ Structure the system into components interacting through messages
  - ❑ Asynchronous interactions, initiated by the emitter
  - ❑ Interactions are deterministic and non continuous

# Style characterization

---

## Elements

- ❑ Emitters components: message senders
- ❑ Receivers components: message consumers
- ❑ Ports: technical interfaces (*send*, *receive*)
- ❑ Connectors: message transporters

## Computing model

- ❑ Communication is initiated by emitters.
- ❑ Messages are consumed at consumers speed.

## Constraints

No constraints on topology.

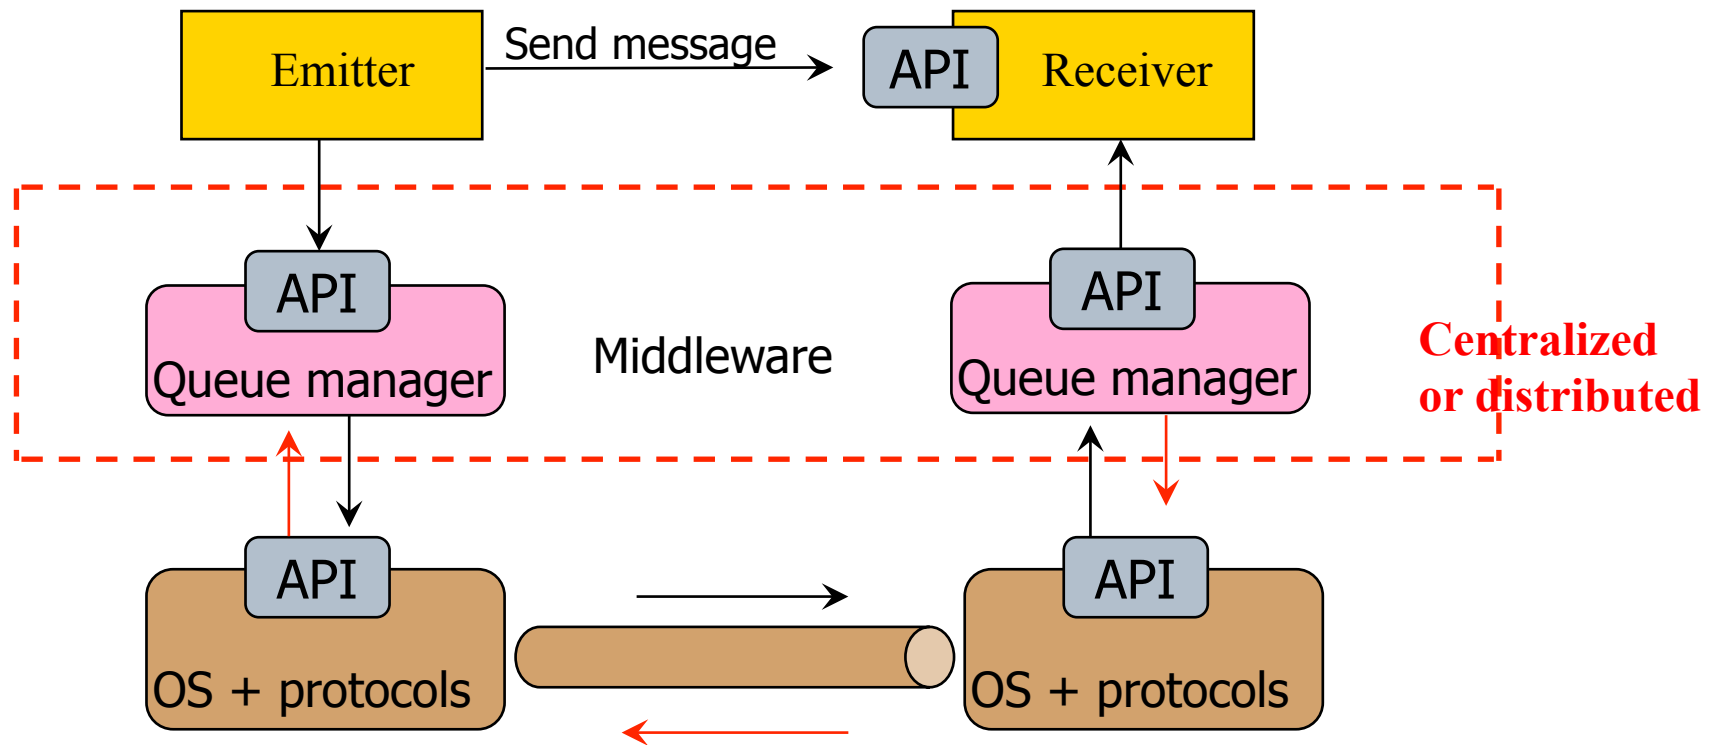

Possible constraints:

- limited number of messages can be received
- message typing

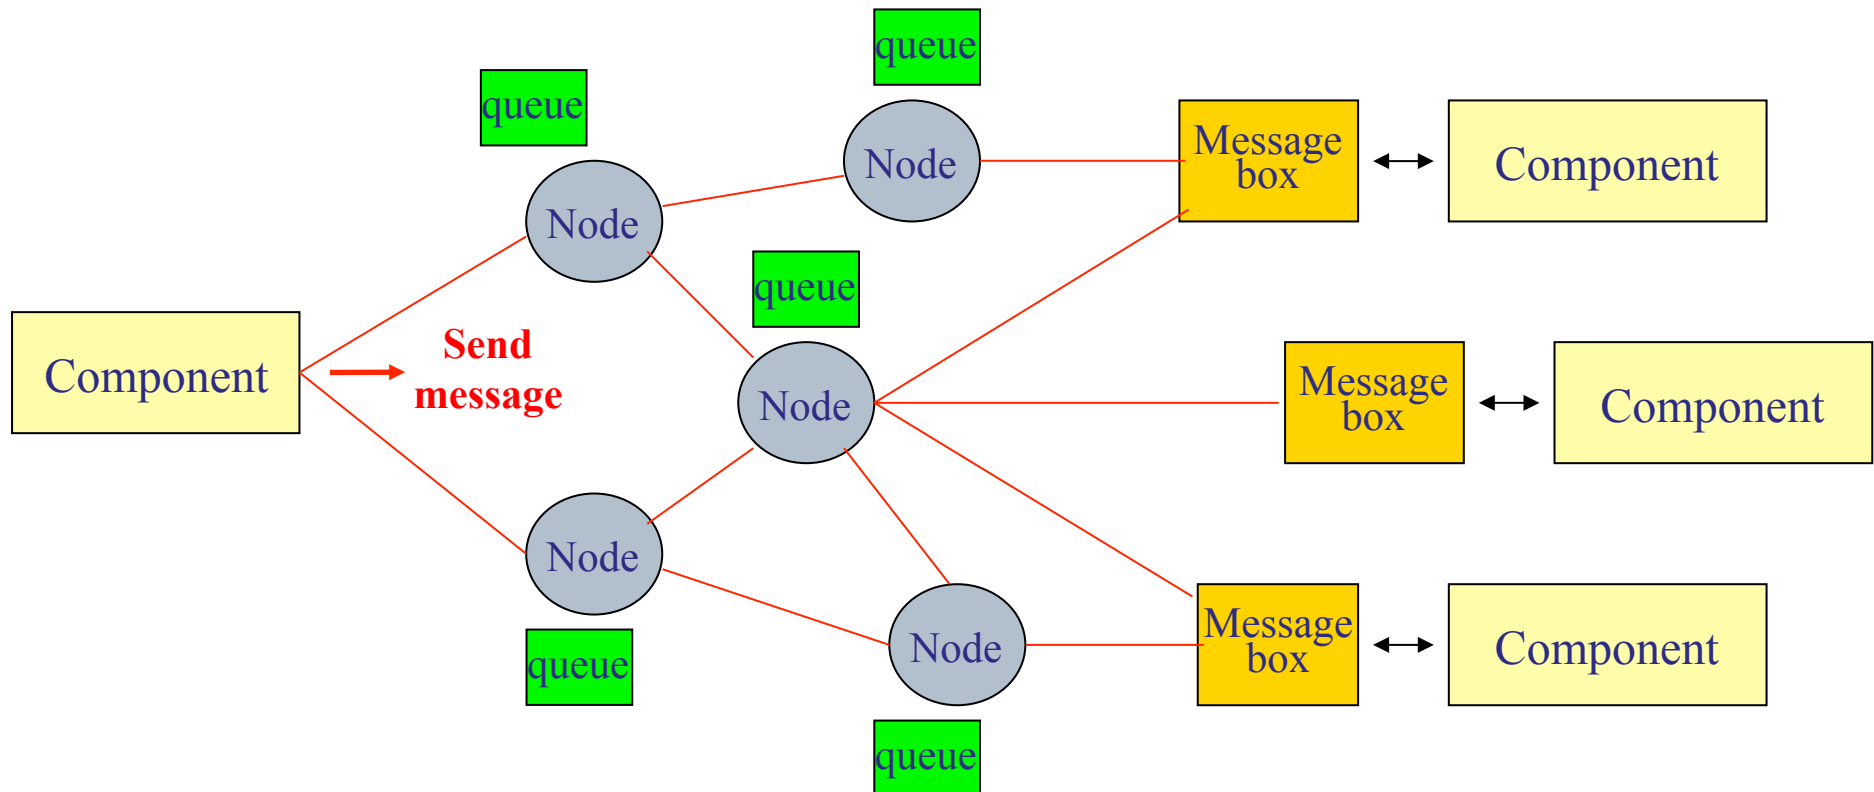

# Implementation

- ❑ Use a middleware
  - ❑ Handle communication and message management

# Implementation – typical architecture

- ❑ Distributed, scalable context

# Advantages

---

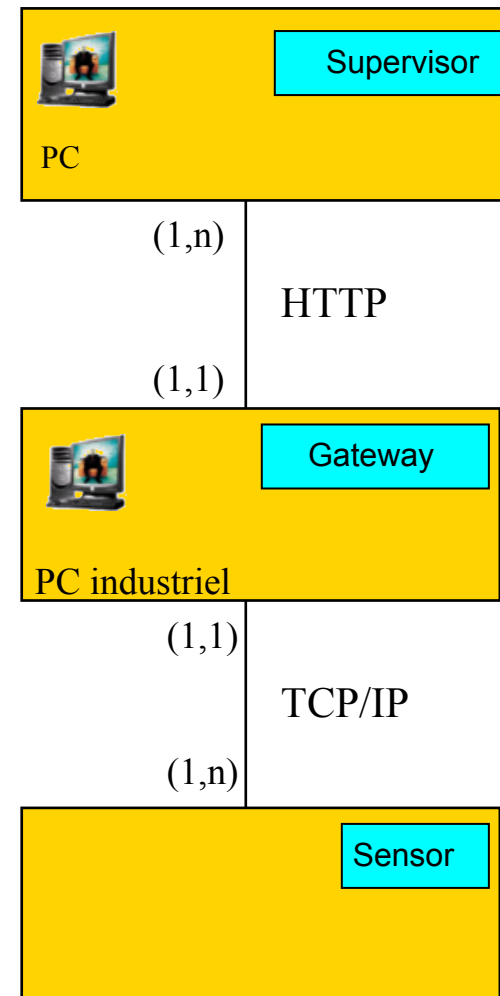

- ❑ Relatively clear
  - ❑ Easy to communicate in simple cases
- ❑ Efficient
  - ❑ Only technical interfaces
  - ❑ No mandatory typing
  - ❑ Communications can be limited
    - ❑ Several kinds of information can be sent in a unique message
- ❑ Decoupling
  - ❑ Weak knowledge about receivers

# Limits

---

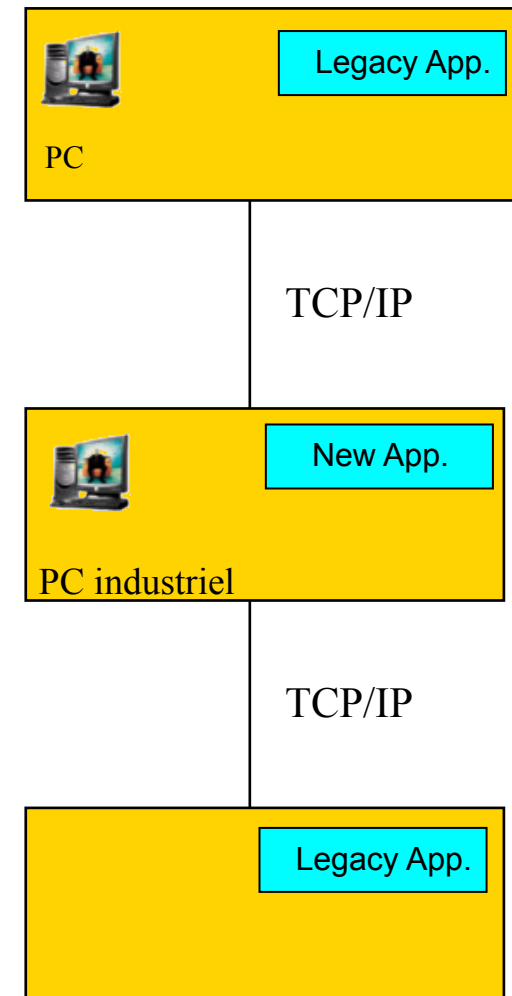

- ❑ May be unclear
  - ❑ Communications are not always explicit – when using multicast for instance
- ❑ Weak regarding SE
  - ❑ No strong typing
  - ❑ Hard to develop, test and debug
- ❑ Message management can become complex
  - ❑ Message persistency, fault handling, ...
  - ❑ A middleware is necessary

# Example: data collection

# Example: application integration

---

# Conclusion

---

- ❑ This is a very popular and useful style
  - ❑ Old and pragmatic
  - ❑ Not perfect in term of SE
  
- ❑ Use it when
  - ❑ Constraint on performance (not too much though!)
  - ❑ Integration of applications with no clear APIs
  - ❑ Asynchronous needs (data collection, unknown frequency rate, ...)

# Outline

---

- ❑ Definition
- ❑ Communication styles
  - ❑ Client / server style
  - ❑ Message-oriented style
  - ❑ Publish / subscribe style
  - ❑ Pipe and filter style
- ❑ Organization styles
  - ❑ Layered style
  - ❑ Shared memory style
- ❑ Conclusion

# Publish / subscribe style

---

- ❑ Structure the system into components interacting through messages with subscription
- ❑ Asynchronous interactions, initiated by the emitter
- ❑ Based on subscriptions on topics
- ❑ Interactions are deterministic and non continuous

# Style characterization

---

## Elements

- ❑ Publishers: message senders
- ❑ Subscribers: message consumers
- ❑ Ports: technical interfaces (*send, receive, subscription management*)
- ❑ Connectors: message transporters

## Computing model

- ❑ Communication is initiated by emitters.
- ❑ Communication only concerns subscribers
- ❑ Messages are consumed at consumers speed.

## Constraints

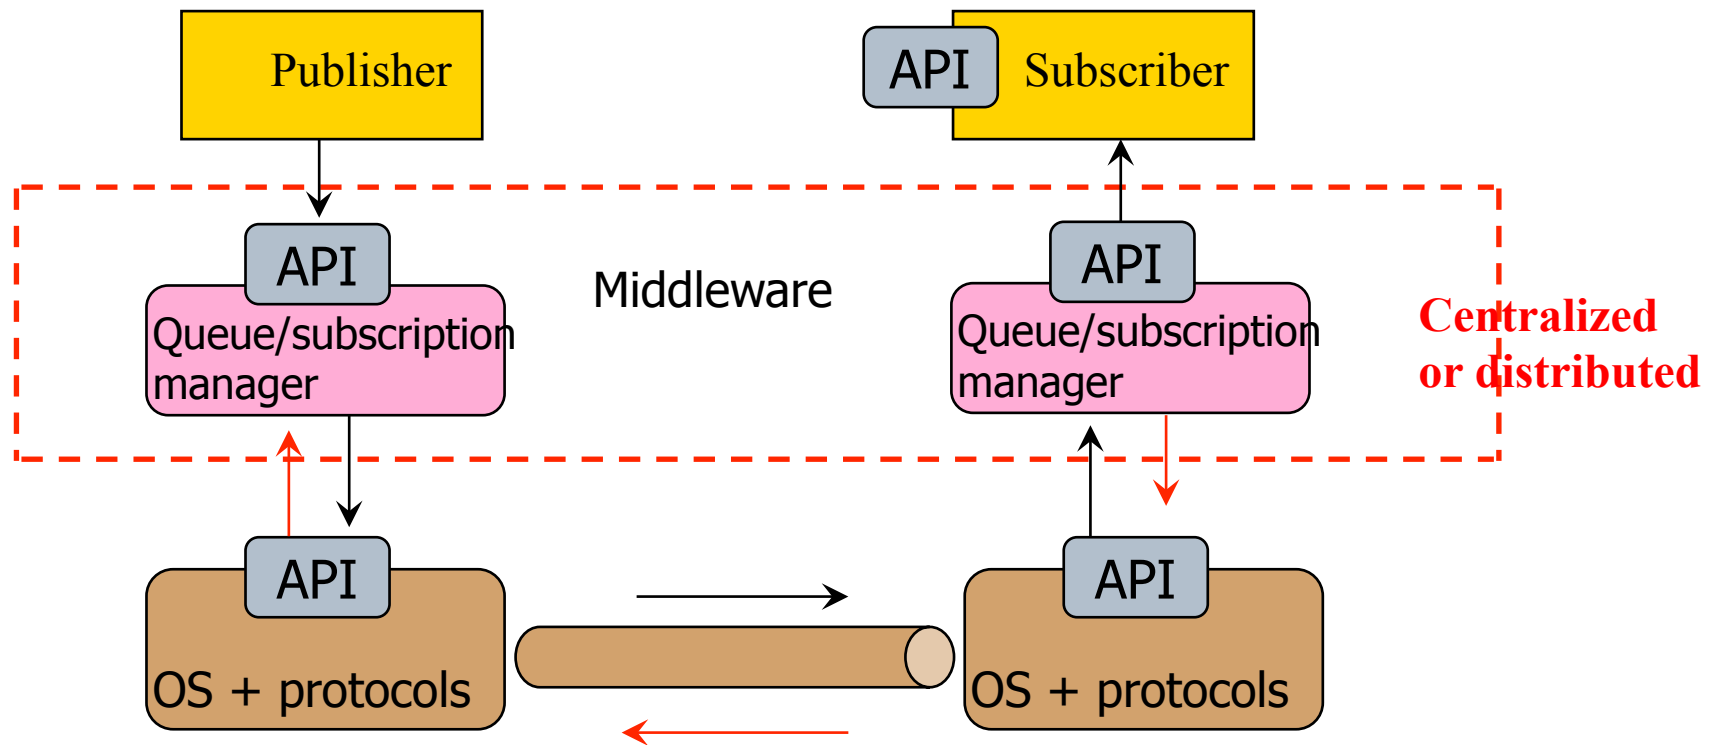

No constraints on topology.

Possible constraints:

- limited number of subscribers
- limited number of topics

# Implementation

- ❑ Use a middleware
  - ❑ Handle communication, message management and subscription management

# Implementation issues

---

- ❑ Interfaces to receive data
  - ❑ One interface per topic: when a component subscribes to a topic, it provides a handle
  - ❑ A single interface for any topic: more analysis work
  - ❑ Taken in charge by the middleware
  
- ❑ Subscription
  - ❑ To a given component: providers are known
  - ❑ To a topic: request sent to the middleware

# Implementation issues – some more

---

- ❑ Issues to be treated
  - ❑ Dynamic creation of topics
  - ❑ Priorities on topics
  - ❑ Different levels of dependabilities
    - ❑ Message sending, persistence, ...
- ❑ Implementing such a middleware is a challenging task

# Advantages

---

- ❑ Efficient
  - ❑ Only technical interfaces
  - ❑ No mandatory typing
  - ❑ Communications are limited
    - ❑ Only interested parties receive messages
- ❑ Decoupling
  - ❑ Links between components are dynamic (it is a data structure coupling)

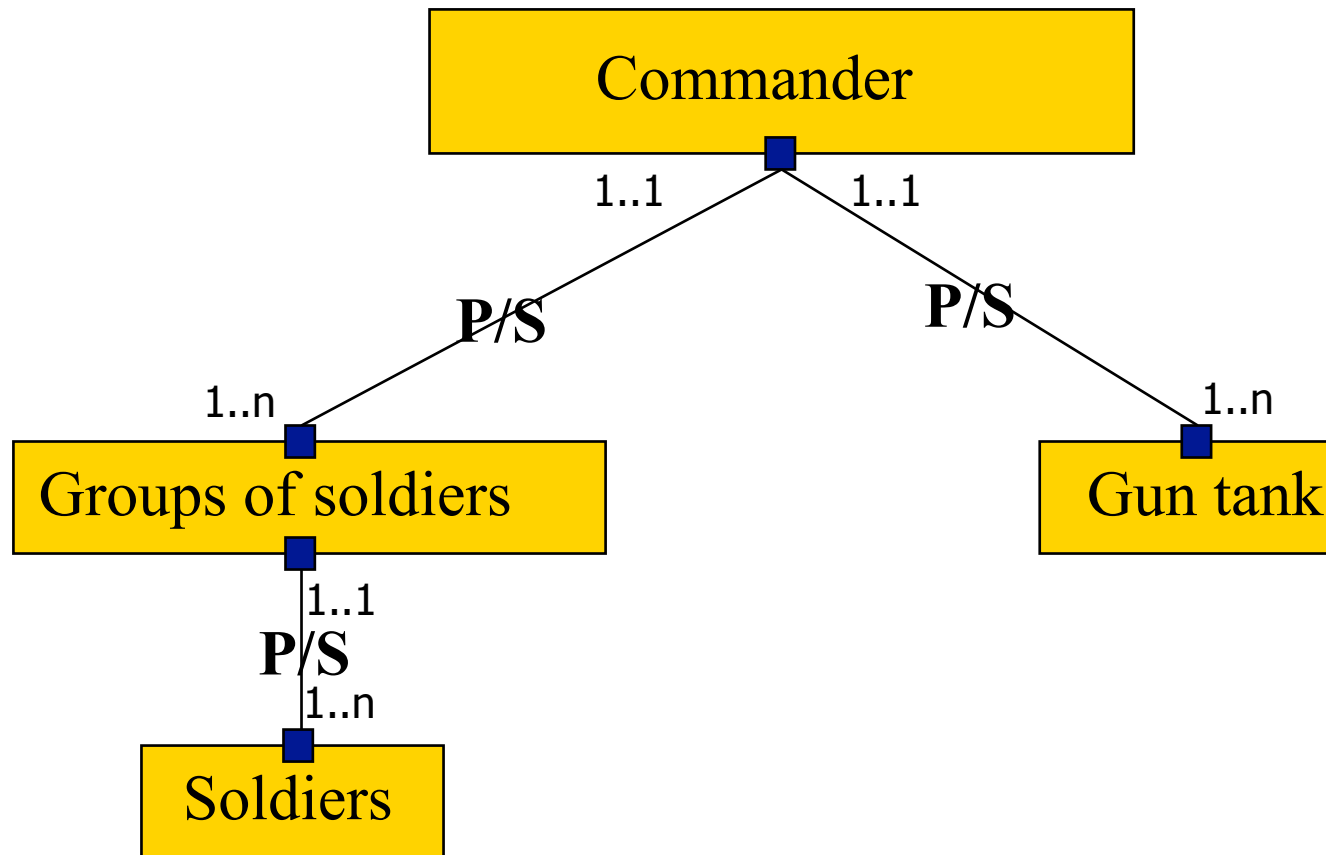

# Limits

---

- ❑ Unclear, hard to understand
  - ❑ Communications are dynamic, not explicit
- ❑ Weak regarding SE
  - ❑ No strong typing
  - ❑ Hard to develop, test and debug
- ❑ Message management is complex
  - ❑ Subscription and topics management
  - ❑ Communication management: distribution, persistence, scheduling, ...
  - ❑ Middleware definitively necessary

# Example: HLA (large-scale simulation)

---

# Conclusion

---

- ❑ This is a recent style, getting popular
  - ❑ Depends on the existence of appropriate middleware
  
- ❑ Use it when
  - ❑ Unknown number of components
  - ❑ Dynamic interactions patterns
    - ❑ Subscriptions evolve wrt context
    - ❑ Topics may evolve too
  - ❑ Need to decouple providers and consumers

# Outline

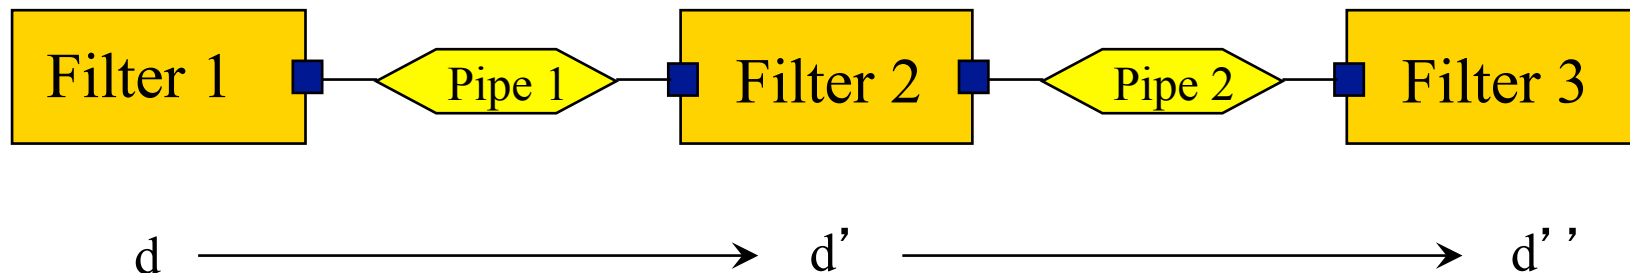

---

- ❑ Definition
- ❑ Communication styles
  - ❑ Client / server style
  - ❑ Message-oriented style
  - ❑ Publish / subscribe style
  - ❑ Pipe and filter style
- ❑ Organization styles
  - ❑ Layered style
  - ❑ Shared memory style
- ❑ Conclusion

# Pipe & Filter style

---

- ❑ Structure the system into components interacting through data flows
  - ❑ Asynchronous interactions, initiated by the emitter
  - ❑ Interactions are deterministic and continuous

# Style characterization

---

## Elements

- ❑ Filters: components transforming data
- ❑ Ports: *in* and *out* (several per components)
- ❑ Pipes: connectors transporting data flows

## Computing model

- ❑ Filters transform data coming through the *in* pipes and write them in the *out* pipes.
- ❑ Politics of data consumption may vary and may be complex

## Constraints

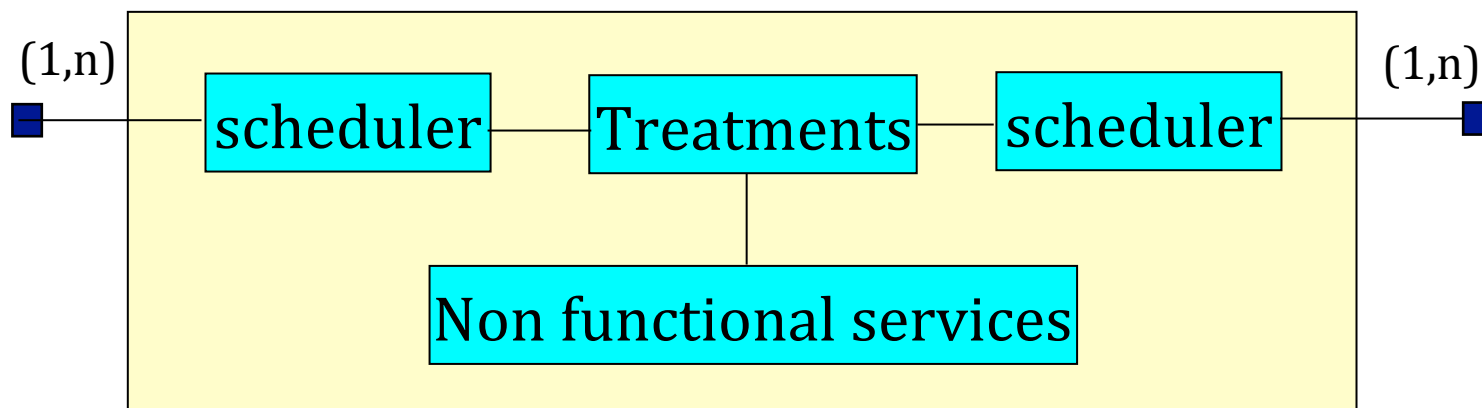

No constraints on the way filters are connected (with pipes). Possible constraints:

- forbid cyclic topology

# Implementation

---

- ❑ Filters may be complex to implement.
- ❑ A framework can be used to
  - ❑ Synchronize inputs
  - ❑ Define consumption strategies
  - ❑ Synchronize outputs

# Advantages

---

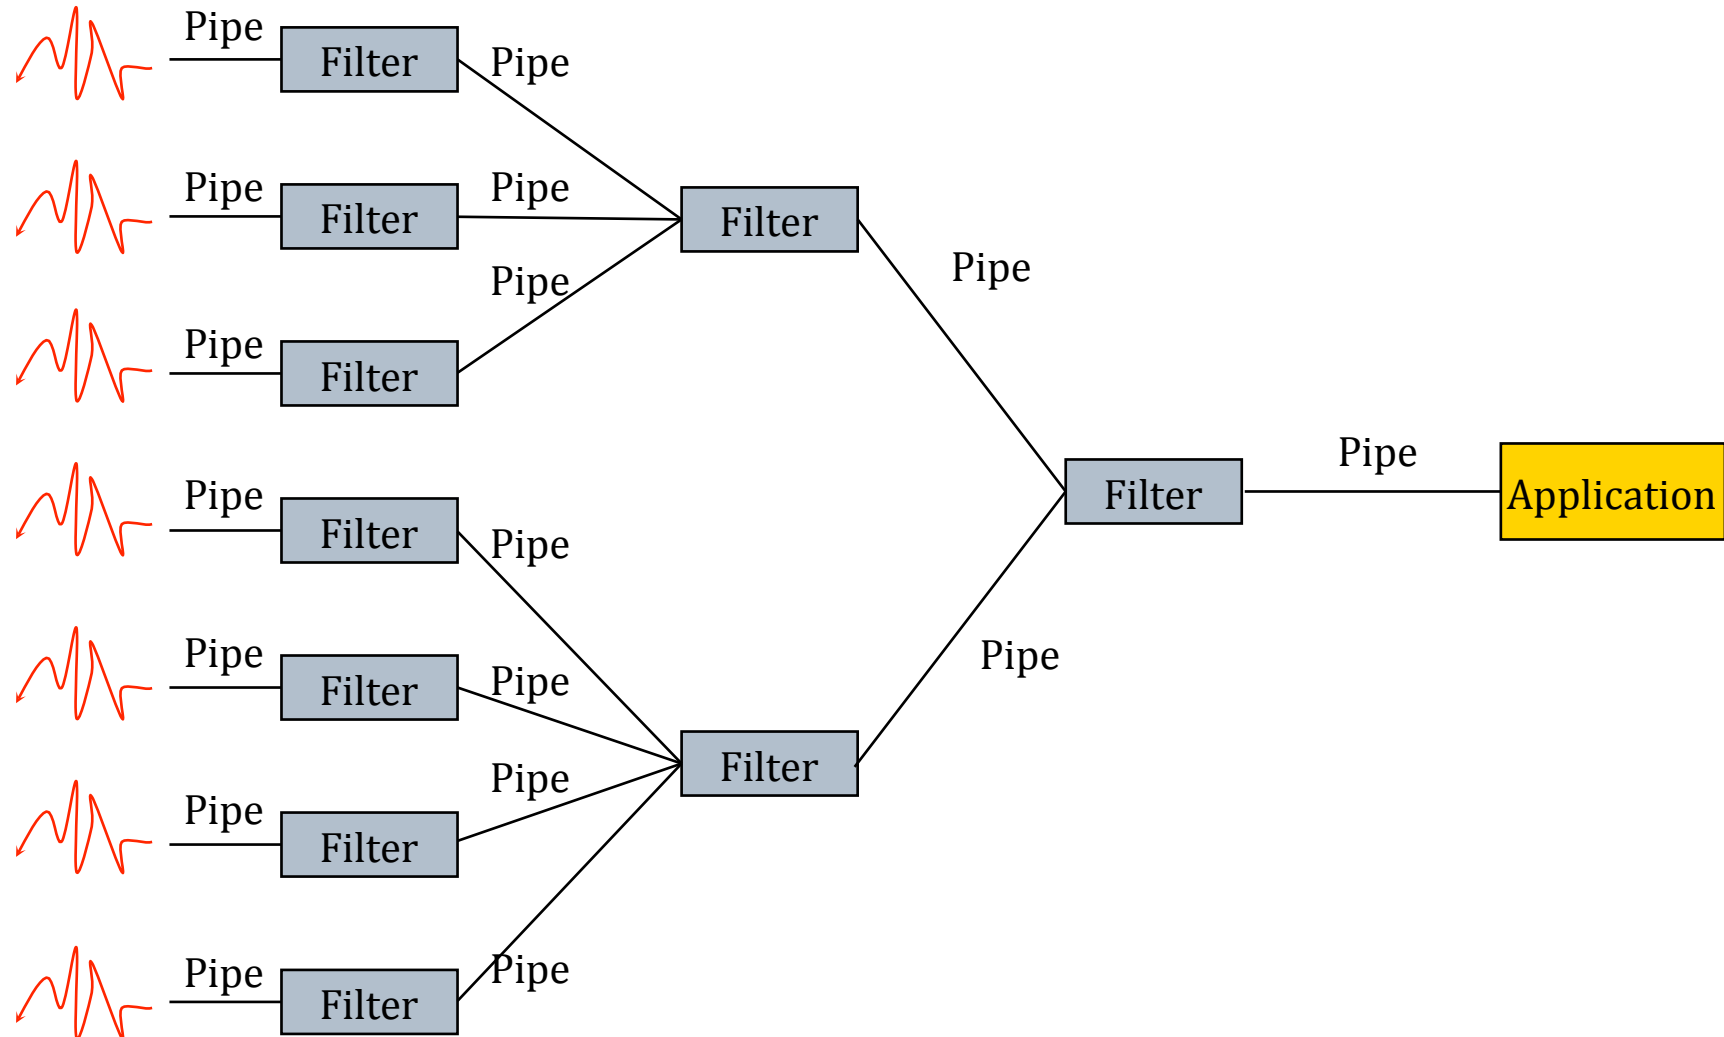

- ❑ Simple and clear
  - ❑ Only two concepts – relatively easy to understand
- ❑ Efficient
  - ❑ No intermediary file (it is really continuous flows of data)
  - ❑ Parallel computing is possible
- ❑ Flexibility
  - ❑ Filters can be improved incrementally
  - ❑ Filters can be changed, new chains can be created
  - ❑ Good for “try and see”

# Limits

---

- ❑ No global information is maintained
  - ❑ Error management is complex
  - ❑ Hard to debug, evaluate, ...
- ❑ Gains with parallelism are sometimes illusive
  - ❑ Pipes can cost more than filters (for distributed systems)
  - ❑ Synchronization and latency problems
- ❑ Reuse
  - ❑ Uniform data format is needed to reuse, replace filters in a flexible manner

# Example: signal analysis

# Conclusion

---

- ❑ Very popular in businesses focused on data processing
  - ❑ Tools suites have been developed
    - ❑ Build, evaluate, rearrange pipe and filters compositions
- ❑ Use it when
  - ❑ Performance is needed
  - ❑ Architectures are hard to define from the beginning
    - ❑ flexibility

# Outline

---

- ❑ Definition
- ❑ Communication styles
  - ❑ Client / server style
  - ❑ Message-oriented style
  - ❑ Publish / subscribe style
  - ❑ Pipe and filter style
- ❑ Organization styles
  - ❑ Layered style
  - ❑ Shared memory style
- ❑ Conclusion

# Layered style

---

- ❑ Structure the system into layers (components)
  - ❑ Communication is limited to adjacent layers
  - ❑ No constraint on communication type
    - ❑ C/S
    - ❑ Message
    - ❑ Stream, ...
  - ❑ No constraints on control
    - ❑ Push vs. pull

# Style characterization

---

## Elements

- ❑ Layers (components)
- ❑ Ports: technical or business interfaces
- ❑ Connectors: no specification

## Computing model

- ❑ Communication made through adjacent layers.

## Constraints

No constraints on communication types  
No constraints on control

# Advantages

---

- ❑ Simple and clear
  - ❑ Communications are limited
- ❑ Favor good structuration
  - ❑ Abstraction level are naturally concretized
- ❑ Favor standardization
  - ❑ Reuse, development of a COTS market
- ❑ If used with a C/S style, it can lead to excellent SE practices!

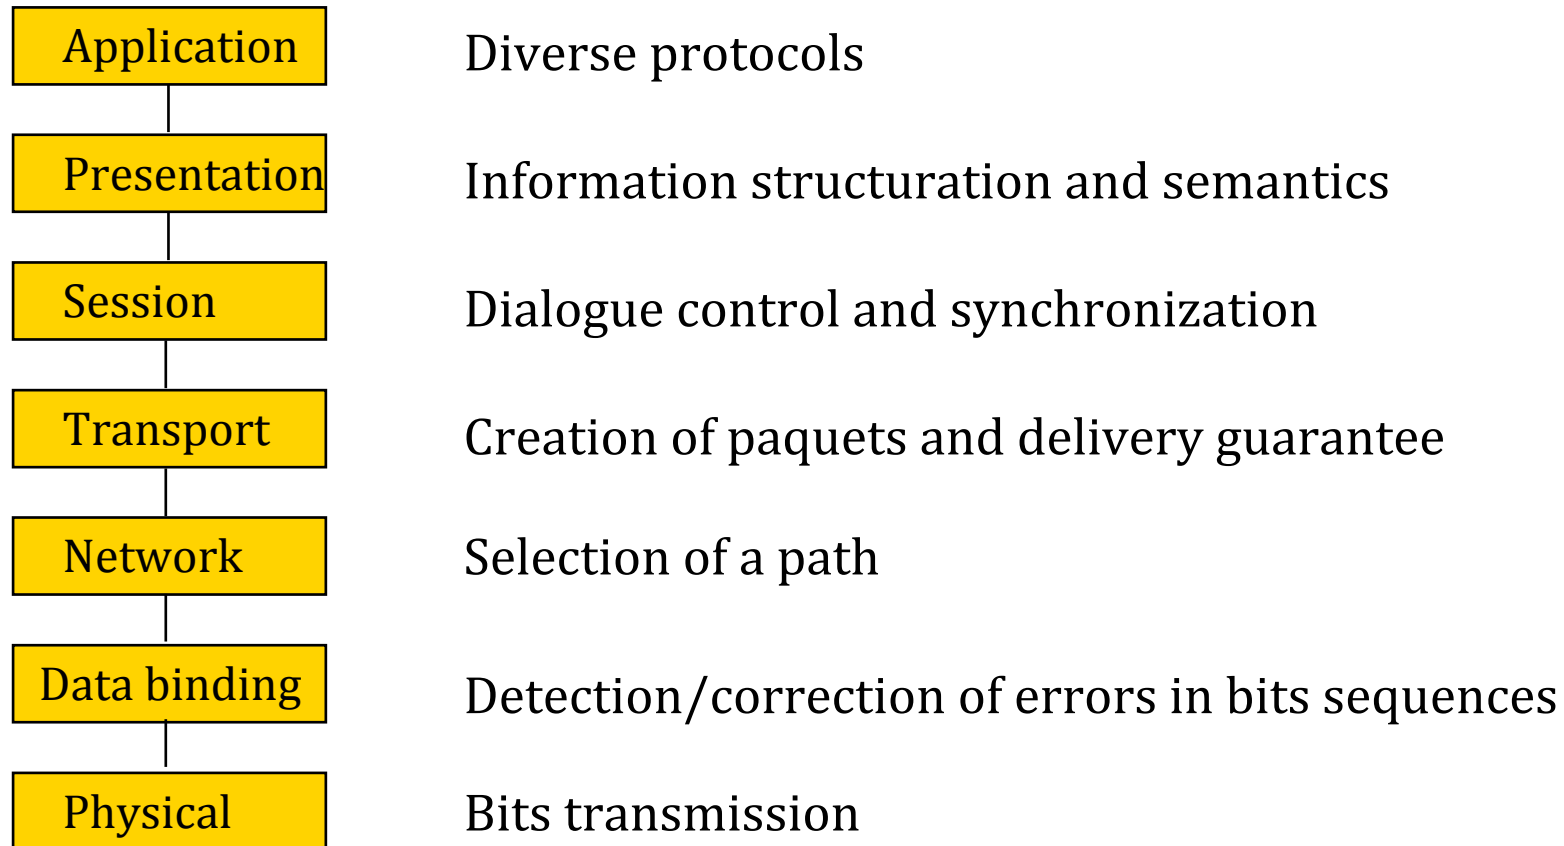

# Limits

---

- ❑ Weak performance
  - ❑ Calculations must go through all the layers
  - ❑ Possible redundancies on the layers
- ❑ Error handling
  - ❑ Errors propagate on several levels
  - ❑ Hard to trace and debug
- ❑ Design is complex
  - ❑ Identify layers corresponding to appropriate abstractions

# Example: communication stacks

---

# Example: information system

---

Presentation

Business Logics

Data

# Conclusion

---

- ❑ Some persons see it as the “best” type of architecture ...
- ❑ Use it when
  - ❑ Levels of abstraction can be identified

# Outline

---

- ❑ Definition
- ❑ Communication styles
  - ❑ Client / server style
  - ❑ Message-oriented style
  - ❑ Publish / subscribe style
  - ❑ Pipe and filter style
- ❑ Organization styles
  - ❑ Layered style
  - ❑ Shared memory style and blackboard style
- ❑ Conclusion

# Shared memory style

---

- ❑ Structure the system into components communicating solely through a shared database
  - ❑ Synchronous or asynchronous interactions, initiated by the emitter
  - ❑ Interactions are deterministic and non continuous

# Style characterization

---

## Elements

- ❑ Computing components
- ❑ Shared memory (a component too)
- ❑ Ports: write and read interfaces
- ❑ Connectors: no specification

## Computing model

- ❑ Communication is made through the shared memory. Components do not know each others.

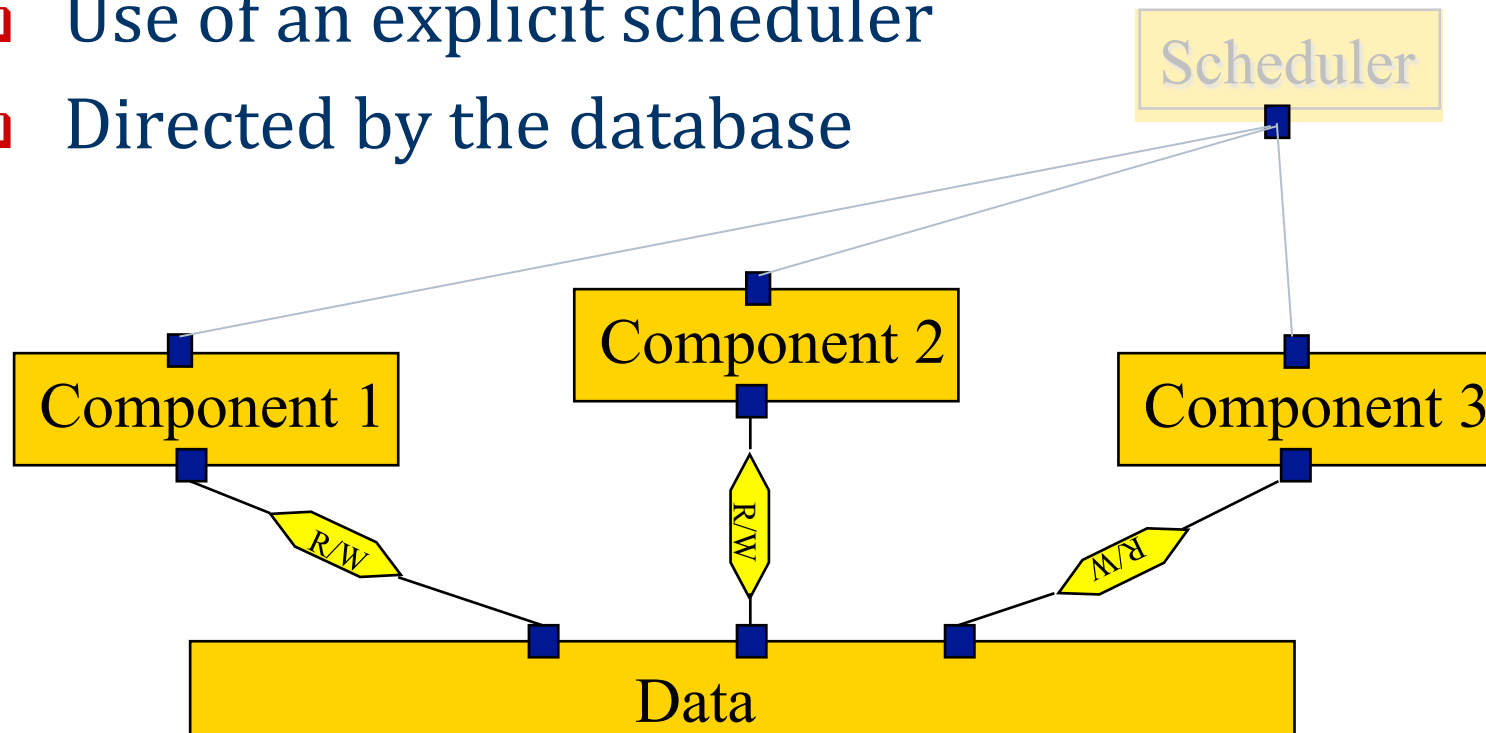

## Constraints

Topology: components are all connected to the shared memory, and only it.

# Implementation

---

- ❑ Key point: activation of components
  - ❑ Use of OS task scheduling
  - ❑ Use of an explicit scheduler
  - ❑ Directed by the database

# Advantages

---

- ❑ Performance
  - ❑ No communication cost
  - ❑ Indirection has a very low cost
  - ❑ Be careful not to have a bottleneck
- ❑ Robustness
  - ❑ Restart is often possible if the shared memory is not damaged
  - ❑ Shared memory is however a sensitive point

# Limits

---

- ❑ Unclear
  - ❑ Communications are not explicit
  - ❑ The state of the shared memory is hard to interpret
- ❑ Security
  - ❑ The shared memory is a key element
- ❑ Maintenance
  - ❑ Modifying the shared memory is very costly
  - ❑ Side effects may be hard to identify

# Example: simulation

---

# Conclusion

---

- ❑ Widespread in embedded systems ...
- ❑ Use it when
  - ❑ Performance!

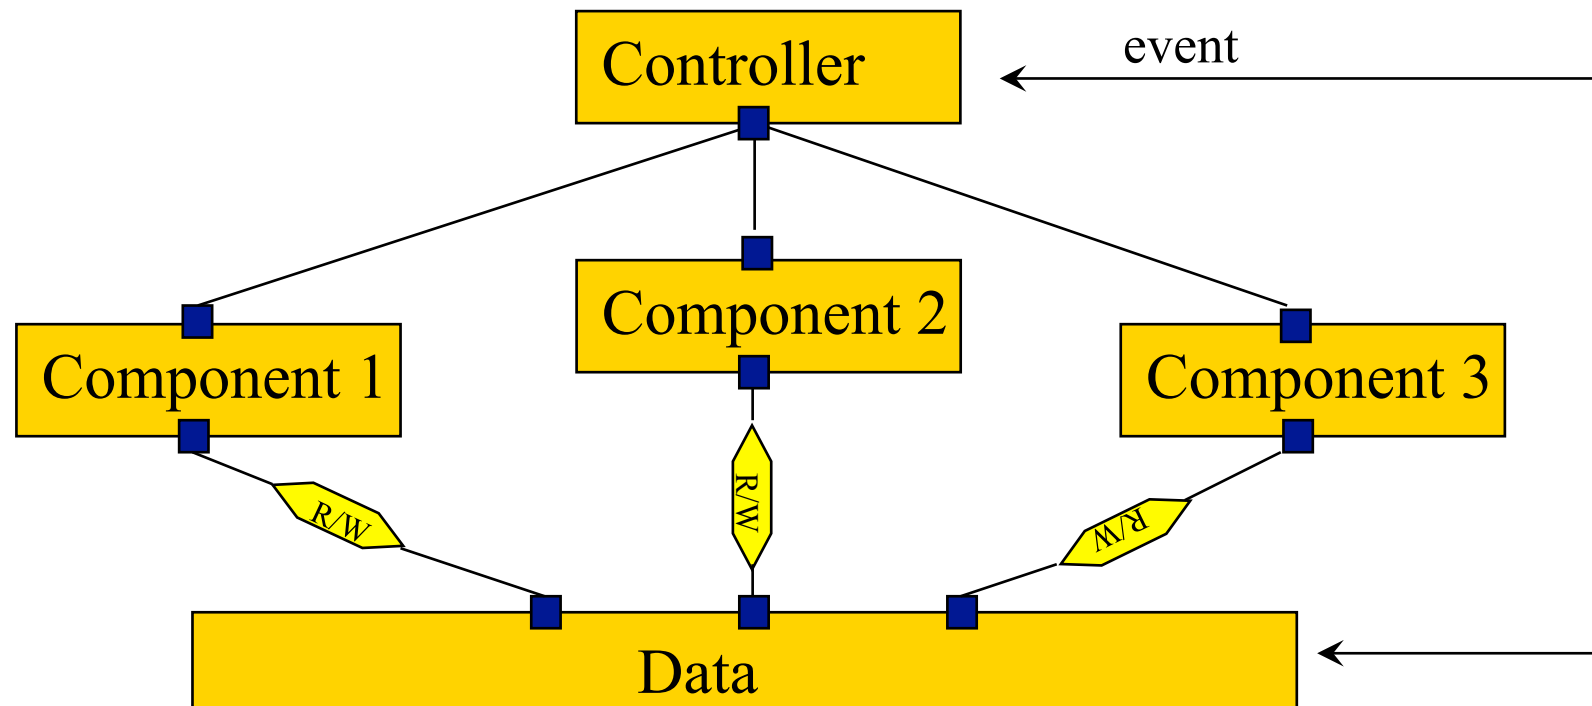

# Outline

---

- ❑ Definition
- ❑ Communication styles
  - ❑ Client / server style
  - ❑ Message-oriented style
  - ❑ Publish / subscribe style
  - ❑ Pipe and filter style
- ❑ Organization styles
  - ❑ Layered style
  - ❑ Shared memory style and blackboard style
- ❑ Conclusion

# Blackboard style

- ❑ Structure the system into components communicating solely through a shared database and opportunistically activated

# Style characterization

---

## Elements

- ❑ Knowledge sources
- ❑ Blackboard
- ❑ Ports: write and read interfaces on KS
- ❑ Ports: event management on Bb and Controller

## Computing model

- ❑ Communication is made through the shared memory. Components do not know each others.
- ❑ Components are activated by the controller
- ❑ Opportunistic control

## Constraints

Topology is constrained:

- KS are all connected to the shared memory
- Controller is connected to KS and blackboard.

# Advantages and limits

---

- ❑ Advantages
  - ❑ Very well suited to exploratory domains
  - ❑ Adaptative
  - ❑ Robust and fault tolerant
- ❑ Limits
  - ❑ Hard to test and debug
  - ❑ Not efficient
  - ❑ Optimal solution is not guaranteed
  - ❑ Control strategy is very complex to define

# Example

---

# Example

---

- ❑ Cycab robot

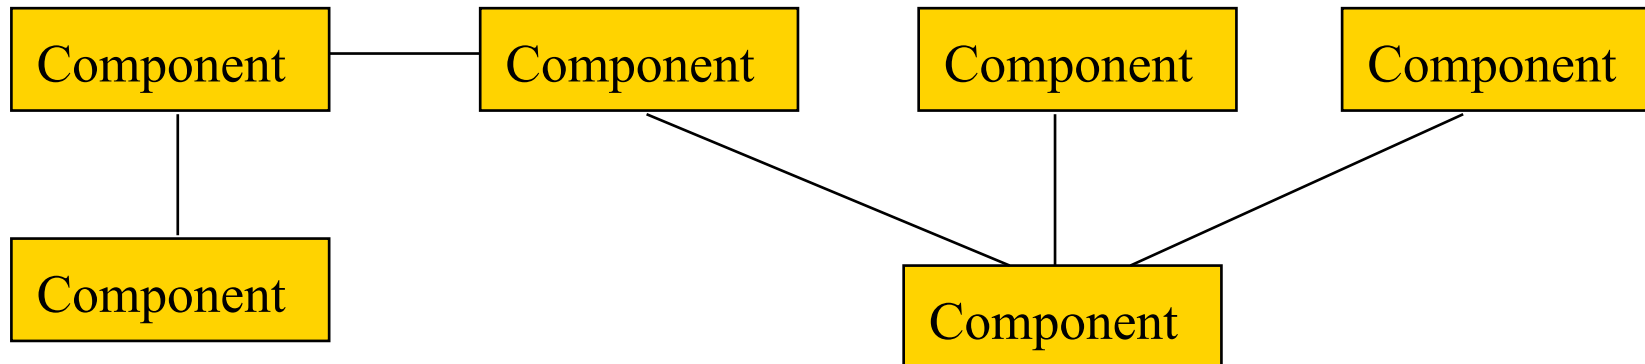

# Outline

---

- ❑ Definition
- ❑ Communication styles
  - ❑ Client / server style
  - ❑ Message-oriented style
  - ❑ Publish / subscribe style
  - ❑ Pipe and filter style
- ❑ Organization styles
  - ❑ Layered style
  - ❑ Shared memory style and blackboard style
- ❑ Conclusion

# Goal

# Styles interactions

---

- ❑ An easily identifiable architecture is needed
  - ❑ Easier to understand, communicate, evaluate
- ❑ Many styles are used in a single system
  - ❑ Architect's role to find the right mixing
